In-class
homework

Conclusion

Lecture topics

- We now begin discussing specific, useful data structures
- These are already well known and understood
- Perfect for learning how a data structure is designed
- We begin with lists

In-class
homework

Conclusion

Introduction

- So far we have been dealing with a single datum in every variable
- For example, integer 0 in variable `i`
- Sometimes we need to store multiple things in the same variable

Conclusion

Introduction

- To solve this problem, we want to have all the data in a single variable
- The variable contains thus an unknown number of values
 - Might be empty
 - Might have only one element
 - Might have hundreds of elements
 - ...

Description

- To solve the issue, we will define an open-ended data structure
- The list is built as a linear chain of **nodes**
- In the simplest implementation, each node has
 - a **value**
 - a reference to the **next** elements
- We never really know how many elements we have in the list until we follow all the references through
- A special case is the empty list, which has no element and no reference to the next elements

```

1 +---+---+   +---+---+   +---+---+   +---+---+
2 | 3 | ----->| 7 | ----->| 4 | ----->|   |   |
3 +---+---+   +---+---+   +---+---+   +---+---+

```

Description

- Consider a list with elements 3, 7, and 4
- We need four nodes (the last is empty), all referencing the next

Description

- A list of values is built as either of:
 - An empty list `Empty`
 - A non-empty list containing the current value `v` and the rest of the list `vtail` `Node(v,tail)`
- **A list with three integers would be?**

Description

- A list of values is built as either of:
 - An empty list `Empty`
 - A non-empty list containing the current value `v` and the rest of the list `vtail` `Node(v,tail)`
- **A list with three integers would be?**
`Node(1,Node(2,Node(3,Empty)))`
- **A list with two integers would be?**

Description

- A list of values is built as either of:
 - An empty list `Empty`
 - A non-empty list containing the current value `v` and the rest of the list `vtail Node(v,tail)`
- **A list with three integers would be?**
`Node(1,Node(2,Node(3,Empty)))`
- **A list with two integers would be?**
`Node(1,Node(2,Empty))`
- **An empty list would be?**

Description

- A list of values is built as either of:
 - An empty list `Empty`
 - A non-empty list containing the current value `v` and the rest of the list `vtail` `Node(v,tail)`
- **A list with three integers would be?**
`Node(1,Node(2,Node(3,Empty)))`
- **A list with two integers would be?**
`Node(1,Node(2,Empty))`
- **An empty list would be?** `Empty`
- ...

Description

- A list of values offers us three pieces of information:
 - A boolean `IsEmpty` indicating whether or not the list is empty
 - The value `Value` of the current element of the list in case it is **not empty**
 - The rest `Tail` of the list in case it is **not empty**
- Given a list `x`
 - **We can check if it is empty with?**

Description

- A list of values offers us three pieces of information:
 - A boolean `IsEmpty` indicating whether or not the list is empty
 - The value `Value` of the current element of the list in case it is **not empty**
 - The rest `Tail` of the list in case it is **not empty**
- Given a list `x`
 - **We can check if it is empty with?** `x.IsEmpty`
 - **We can read print its first value with?**

Description

- A list of values offers us three pieces of information:
 - A boolean `IsEmpty` indicating whether or not the list is empty
 - The value `Value` of the current element of the list in case it is **not empty**
 - The rest `Tail` of the list in case it is **not empty**
- Given a list `x`
 - **We can check if it is empty with?** `x.IsEmpty`
 - **We can read print its first value with?** `x.Value`
 - **We can print its second value with?**

Description

Conclusion

Introduction

- How is this done in Python?
- We shall build two data structures that, together, make up arbitrary lists
- We begin with the blueprints

The blueprint (**THIS IS NOT CODE!**)

Classes

TEAM
INFDEV

Introduction

Problem
discussion

General idea

Technical
details

In-class
homework

Conclusion

```
1  Abstraction Empty =  
2      IsEmpty, which is always true  
3  
4  Abstraction Node =  
5      IsEmpty, which is always true  
6      Value, which contains the datum of this element of the list  
7      Tail, which contains the remaining nodes of the list
```

Introduction

The blueprint (**THIS IS NOT CODE!**)

Classes

TEAM
INFDEV

Introduction

Problem
discussion

General idea

Technical
details

In-class
homework

Conclusion

```
1  Abstraction Empty =  
2      IsEmpty, which is always true  
3  
4  Abstraction Node =  
5      IsEmpty, which is always true  
6      Value, which contains the datum of this element of the list  
7      Tail, which contains the remaining nodes of the list
```

Introduction

- How do we translate this to Python?

The blueprint (**THIS IS NOT CODE!**)

INFDEV

Introduction

Problem
discussion

General idea

Technical
details

In-class
homework

Conclusion

```
1  Abstraction Empty =  
2      IsEmpty, which is always true  
3  
4  Abstraction Node =  
5      IsEmpty, which is always true  
6      Value, which contains the datum of this element of the list  
7      Tail, which contains the remaining nodes of the list
```

Introduction

- How do we translate this to Python?
- Each abstraction becomes a class
- Each field is assigned under `__init__` to `self`

The actual code

Classes

TEAM
INFDEV

Introduction

Problem
discussion

General idea

Technical
details

In-class
homework

Conclusion

```
1 class Empty:
2     def __init__(self):
3         self.IsEmpty = True
4     Empty = Empty()
5
6 class Node:
7     def __init__(self, value, tail):
8         self.IsEmpty = False
9         self.Value = value
10        self.Tail = tail
```

Note: we are switching to Python 3!

Lecture topics

- What we solved today was the issue of representing multiple data inside a single variable
- We used a simple data structure, the **list**
- We showed how we can consume (use) the list through looping
